Swellings: Neck

Neck lumps

The lymphoid system is the essential basis of immune defences and comprises predominantly bone marrow, spleen, thymus and lymph nodes. Tissue fluid drains into lymph nodes which act as 'filters' of antigens and, after processing in the nodes, drains into lymph nodes which act as 'filters' for malignant disease. Lymphocytes and antigens pass into the cortex through the afferent lymphatics, are 'filtered' and pass out from the medulla through the efferent lymphatics. The cortex contains B cells aggregated into primary follicles; following stimulation by antigen these develop a focus of active proliferation (germinal centre) and are termed secondary follicles. These follicles are in intimate contact with antigen-presenting dendritic cells. The paracortex contains T cells, and the medulla contains T and B cells.

Causes of lymph node enlargement

Many diseases can present with lesions in the neck but the most common are lesions involving the lymph nodes (Table 1).

Lymph nodes enlarge in oral infections or local infections in the drainage area (virtually anywhere in the head and neck). Most common is an enlarged jugulo-digastric (tonsillar) lymph node, inflamed secondary to a viral upper respiratory tract infection. Children and young adults are predominantly affected (Table 2). Enlarged cervical lymph nodes may also be related to malignant disease in the drainage area (eg carcinoma) or may be a manifestation of systemic disease (eg HIV/AIDS). Adults are predominantly affected.

Examination of cervical lymph nodes

The examination of lymph nodes in the neck is an important part of every orofacial examination. About one-third of all the lymph nodes in the body are in the neck and dental surgeons can often detect serious disease through their examination of the neck.

Specialist referral may be indicated if the Practitioner feels:

- The diagnosis is unclear;
- A serious diagnosis is possible;
- Systemic disease may be present;
- Unclear as to investigations indicated;
- Complex investigations unavailable in primary care are indicated;
- Unclear as to treatment indicated;
- Treatment is complex;
- Treatment requires agents not readily available;
- Unclear as to the prognosis;
- The patient wishes this.

This series provides an overview of current thinking in the more relevant areas of Oral Medicine, for primary care practitioners.

The series gives the detail necessary to assist the primary dental clinical team caring for patients with oral complaints that may be seen in general dental practice. Space precludes inclusion of illustrations of uncommon or rare disorders.

Approaching the subject mainly by the symptomatic approach, as it largely relates to the presenting complaint, was considered to be a more helpful approach for GDPs rather than taking a diagnostic category approach. The clinical aspects of the relevant disorders are discussed, including a brief overview of the aetiology, detail on the clinical features and how the diagnosis is made, along with guidance on management and when to refer, in addition to relevant websites which offer further detail.

Inspection of the neck, looking particularly for swellings or sinuses, should be followed by careful palpation of the thyroid gland and all the lymph nodes, searching for swelling or tenderness.

It is prudent to adopt a systematic and methodical approach examining different lymph node groups in turn:

- Submental;
- Submandibular;
- Pre-auricular/parotid;
- Occipital;
- Deep cervical chain.

Both anterior and posterior cervical nodes should be examined as well as other nodes, liver and spleen if systemic disease is a possibility. Most disease in lymph nodes is detected in the anterior triangle of the neck, which is bounded superiorly by the mandibular border, posteriorly and inferiorly by the sternomastoid muscle, and anteriorly by the midline of the neck. Nodes in this site drain most of the head and neck, except the occiput and back of neck. Lymphadenopathy in the anterior triangle of the neck alone is often due to local disease, especially if the nodes are enlarged on only one side.

A limited number of lymph nodes swell usually because they are involved in an immune response to an infectious agent in the area of drainage and nodes are then often firm, discrete and tender, but are mobile (lymphadenitis). The focus of inflammation can usually be found in the drainage area, which is anywhere on the face, scalp and nasal cavity, sinuses, ears, pharynx and oral cavity. Lymph nodes that are tender may be inflammatory, leukaemia or lymphoma; those that are increasing in size and are hard may be malignant.

Lymph nodes may show reactive
Inflammatory Infective Local Bacterial Local infections in the head and neck Viral Viral respiratory infections Herpes simplex Herpes zoster Herpangina Rubella Systemic Bacterial Syphilis Tuberculosis Atypical mycobacterioses Cat scratch fever Brucellosis Viral Glandular fever syndromes (EBV, CMV, HIV, HHV-6) Protozoal Toxoplasmosis Probably Infective Mucocutaneous lymph node syndrome (Kawasaki disease) Non-Infective Sarcoidosis Crohn's disease Connective tissue diseases Malignancy Primary Leukaemias Secondary Lymphomas Metastases Other Drugs, eg phenytoin

- hyperplasia to a malignant tumour in the drainage area, or swelling because of metastatic infiltration. The latter may cause the node to feel distinctly hard, and it may become bound down to adjacent tissues (‘fixed’), may not be discrete, and may even, in advanced cases, ulcerate through the skin. The neoplasms that frequently metastasise to cervical lymph nodes are oral squamous carcinoma (Article 3), nasopharyngeal carcinoma, tonsillar cancer and thyroid tumours.

Usually one or more anterior cervical nodes are involved, often unilaterally in oral neoplasms anteriorly in the mouth, but otherwise not infrequently bilaterally.

Generalized lymphadenopathy with or without enlargement of other lymphoid tissue, such as liver and spleen (hepatosplenomegaly), suggests a systemic cause.

The local cause may not always be found despite a careful search. For example, children occasionally develop a *Staphylococcus aureus* lymphadenitis (usually in a submandibular node) in the absence of any obvious portal of infection.

More serious is the finding of an enlarged node suspected to be malignant but where the primary neoplasm cannot be found. Nasopharyngeal or tonsillar carcinomas are classic causes of this and an ENT opinion should therefore be sought. Clinically unsuspected tonsillar cancer is a common cause of metastasis in a cervical node. Biopsy of the tonsil may reveal a hitherto unsuspected malignancy.

Rare causes of cervical metastases include metastases from stomach or even testicular tumours to lower cervical nodes. However, in some patients with a malignant cervical lymph node, the primary tumour is never located.

Lymph nodes may also swell when there are disorders involving the immune system more generally, such as the glandular fever syndromes, HIV/AIDS and related syndromes, various other viral infections; bacterial infections such as syphilis and tuberculosis; and parasites such as toxoplasmosis. In the systemic infective disorders the nodes are usually firm, discrete, tender and mobile. Lymph nodes may also swell in non-infective lesions such as sarcoidosis, mucocutaneous lymph node syndrome, and neoplasms such as lymphomas and leukaemias (Table 1). In the latter instances, and in the glandular fever syndromes (where there is lymphadenopathy often together with sore throat and fever; Table 3), there is usually enlargement of many or all cervical lymph nodes and in some there is involvement of the whole reticuloendothelial system, with generalized lymph node enlargement (detectable clinically in neck, groin and axilla) and enlargement of the liver and spleen (hepatosplenomegaly). In the lymphomas particularly, the nodes may be rubbery, matted together and fixed to deeper structures.

**Management**

A Specialist opinion is generally indicated.

College of Medicine and Veterinary Medicine
Primary Dental Care
Postgraduate study at the Edinburgh Dental Institute

Primary Dental Care
MSc/Diploma/Certificate by online distance learning
A part-time online distance learning programme for primary care dentists.

Join our online community of students from around the world
This part-time online programme provides Masters-level education for primary care dentists with a particular emphasis on advanced general practice. The structure of the degree is designed to meet the needs of dental practitioners from all over the world.

Why study with us?
• competitively-priced programme - generous bursaries are available for those commencing study in February 2014
• we offer a conjoint examination with the Royal College of Surgeons of Edinburgh MPDC
• programme is greatly endorsed by current students - visit the website to read student testimonials

Edinburgh Dental Institute and distance learning
Some very exciting and innovative teaching material has been developed for this programme, providing you with a cutting-edge, dynamic learning environment and access to excellent resources. This course is eligible for 90 credits within the FGDP (UK) career pathway.

Entry requirements
A Bachelor of Dental Surgery degree or equivalent primary dental qualification and current practice in a primary dental care clinical environment is essential.
